Bis-(aminomethyl)ethers (1-4) have been employed as molecular scavengers for cyanides. They are theoretically studied herein at DFT, thus enabling a theoretical study in order to elucidate why the efficiency as scavenger depends on the substituent placed at the nitrogen atom. The local softness ( $\mathrm{s}^{+}$) value for C 2 from electrostatic potential analysis (ESP) shows that the following decreasing order of reactivity is in accordance with the experimental yield values: 4, 1, $\mathbf{2}$ and $\mathbf{3} .1290$ runs considering four to ten parameters such as N3-C2 and C2-O1 bond lengths, HOMO and LUMO energies, GAP, dipolar moment, partition coefficient, atomic charge, local softness, global hardness, electronegativity and ${ }^{13} \mathrm{C}$ NMR chemical shift were taken into account in a structure-activity relationship study. In particular five runs of linear combination of four (run 259), five (run 517), seven (runs 937 and 1063) and eight (run 1214) molecular indexes have shown the best F values, being the run 517 , which present the highest F value 4 to 10 parameters.

Key Words: Local softness, DFT, Molecular descriptor, Molecular reactivity, Scavenger.

## INTRODUCTION

Metallic cyanides are among the most common corrosive pollutants in crude oil ${ }^{1-3}$. In order to eliminate the cyanide ions in the petroleum feedstock, some scavengers of cyanides have been synthesized ${ }^{4}$. A strecker intermediates that act as scavengers of cyanides were synthesized ${ }^{5}$; which have shown different chemical reactivity, measured as reaction yield, between 66 and $94 \%$, when cyanide is the nucelophile species and thus this can be considered as their activity as cyanide scavengers.

On another hand, the electron density $\rho(\mathrm{r})$ distribution is a fundamental concept to understand the reactivity of molecular entities and therefore, it can explain the phenomena of nucleophilic, electrophilic and radical attacks on a particular structure. The frontier-electron density theory of chemical reactivity by Fukui ${ }^{6}$ explained the importance of the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) in the chemical reactions. Therefore, the Fukui function $f(\mathrm{r})$ and local softness $\mathrm{s}(\mathrm{r})$ are of great interest in chemical reactions, because these parameters could describe
the most reactive site in a given molecular species. The $f(\mathrm{r})$ function for a molecule can be defined as ${ }^{7}$ :

$$
\begin{equation*}
\mathrm{f}(\mathrm{r})=(\delta \mu / \delta v(\mathrm{r}))_{\mathrm{N}}=(\partial \rho(\mathrm{r}) / \partial \mathrm{N})_{v(\mathrm{r})} \tag{1}
\end{equation*}
$$

where, $\mu$ is the chemical potential, N is the number of electrons, $v(r)$ is the potential acting on an electron due to all nuclei and $\rho(\mathrm{r})$ is the electron density. The $\rho(\mathrm{r})$ measures how sensitive a chemical potential is to an external perturbation at a particular point. Thus, $f(r)$ indirectly gives the reactivity of a particular site and hence acts as a reactivity index. Considering the fact that $\rho(\mathrm{r})$ is a discontinuous function of N , two different types of $f(\mathrm{r})$ can be defined for any atom or molecule corresponding to a nucleophilic and electrophilic attack. However, the evaluation of these $f(\mathrm{r})$ values is quite intricate. A simple procedure to calculate $f_{\mathrm{k}}$ (condensed Fukui function) was proposed by Yang and Mortie, an alternative for $f(\mathrm{r})$, based on the Mulliken population analysis (MPA) and the finitedifference approximation of eqn. (1). In a finite-difference approximation, for a system of N electrons, the $f(\mathrm{r})$ values are given as:

$$
\begin{equation*}
\mathrm{f}^{+}(\mathrm{r})=\mathrm{q}_{\mathrm{k}}\left(\mathrm{~N}_{0}+1\right)-\mathrm{q}_{\mathrm{k}}\left(\mathrm{~N}_{0}\right) \text { for a nucleophilic attack } \tag{2}
\end{equation*}
$$

$\mathrm{f}^{-}(\mathrm{r})=\mathrm{q}_{\mathrm{k}}\left(\mathrm{N}_{0}\right)-\mathrm{q}_{\mathrm{k}}(\mathrm{N}-1)$ for an electrophilic attack where, $\mathrm{q}_{\mathrm{k}}\left(\mathrm{N}_{0}\right), \mathrm{q}_{\mathrm{k}}\left(\mathrm{N}_{0}-1\right)$ and $\mathrm{q}_{\mathrm{k}}\left(\mathrm{N}_{0}+1\right)$ represent the electronic population in the k atom for the $\mathrm{N}_{0}, \mathrm{~N}_{0}-1$ and $\mathrm{N}_{0}+1$ electron system, respectively.

The local softness parameter is defined as:

$$
\begin{equation*}
\mathrm{s}(\mathrm{r})=f(\mathrm{r}) \mathrm{S} \tag{4}
\end{equation*}
$$

where, $S$ is the global softness. Furthermore, the three approximate atomic $f(\mathrm{r})$ indexes, when they are multiplied by S , provide two different local softnesses for any particular atom (k), which can be written as:

$$
\begin{align*}
& \mathrm{s}_{\mathrm{k}^{+}}=\left[\mathrm{q}_{\mathrm{k}}\left(\mathrm{~N}_{0}+1\right)-\mathrm{q}_{\mathrm{k}}\left(\mathrm{~N}_{0}\right)\right] \mathrm{S}  \tag{5}\\
& \mathrm{~S}_{\mathrm{k}^{-}}=\left[\mathrm{q}_{\mathrm{k}}\left(\mathrm{~N}_{0}\right)-\mathrm{q}_{\mathrm{k}}\left(\mathrm{~N}_{0}-1\right)\right] \mathrm{S} \tag{6}
\end{align*}
$$

Finally, the $\Delta f(\mathrm{r})$ descriptor defined as the difference of the nucleophilic Fukui function $f^{4}(\mathrm{r})$ and the electrophilic Fukui function $f(\mathrm{r})^{8}$. The sign of the $\Delta f(\mathrm{r})$ describes the electrophile $(\Delta f(\mathrm{r})>0)$ and nucleophile $(\Delta f(\mathrm{r})<0)$ zones within a molecule.

On the other hand, it is well known that quantum chemistry enables tools to obtain chemical descriptors (molecular orbital energies, gap, atomic charge, etc.) these can be employed to carry on quantitative structure-activity relationships (QSAR). This analysis has been widely employed in the biological area, however, some works have been published in the field of corrosion science ${ }^{9-12}$, or other scientific and industrial fields where a particular activity is acknowledged and is intended to be optimized in such a way.

In this work, we present a study performed at DFT for four already known and tested molecular scavengers. This survey takes into account the analysis of reactivity parameter (local softness) in order to relate this with the scavenging activity. In this work, we have done a structure-activity study ${ }^{13}$ in order to account the factors that govern such activity.

## EXPERIMENTAL

DFT calculations implemented in the Gaussian 98 program package ${ }^{14}$ were done using to carry out the optimization of the structures by using a B3LYP functional ${ }^{15}$. The B3LYP hybrid functional defines the exchange functional as a linear combination of Hartree-Fock, local and gradient-corrected exchange terms ${ }^{15-19}$. The $6-31 \mathrm{G}+(\mathrm{d})$ basis set was employed in this work, where diffuse functions were employed because they are known to supply a better energy value for anionic species. The zeropoint energy correction (ZPE) was calculated at same level of theory in all four molecular cases under study.

The ${ }^{13} \mathrm{C}$ NMR shielding tensors were calculated using the methodology of Gauge Independent Atomic Orbitals (GIAO) ${ }^{20-23}$.

The isotropic shielding values defined as:

$$
\begin{equation*}
\sigma_{\mathrm{iso}}=1 / 3\left(\sigma_{11}+\sigma_{22}+\sigma_{33}\right) \tag{7}
\end{equation*}
$$

where ( $\sigma_{\mathrm{ii}}$ being the principal tensor components) were used to calculate the isotropic chemical shifts ( $\delta$ ) relative to TMS $\left(\delta^{\mathrm{X}}=\sigma^{\text {TMS }}-\sigma^{X}\right)^{24-26}$. Finally, the parameters for the structureactivity study were obtained at B3LYP/6-31G+(d) level, except the $\log \mathrm{P}$ parameter, which was obtained by using Hyper Chem software.

## RESULTS AND DISCUSSION

The synthesis of Strecker intermediates as bis-(aminomethyl)ethers (1-4) 1-4, have already been reported (Fig. 1) ${ }^{5}$. Such compounds could act as non-pollutant scavengers for
sodium cyanide, in water and solvent mixtures, that have a composition similar to -crude oil; in where the efficiency (Eff) for scavenging were of $90.7,65.8,58.8$ and $93.5 \%$ for $\mathbf{1 , 2 , 3}$ and $\mathbf{4}$, respectively. The last one has a pseudo-ephedrine fragment (the most branched $N$ substitution in the whole series) and it shows the highest efficiency as scavenger. Thus, the experimental yield values depend on the structure and thus the reactivity of the employed $\beta$-amino alcohols, not only to form the Strecker intermediates but also to scavenge cyanide ions in order to obtain $N$ substituted glycine derivatives as the non-pollutant species. In this contribution, a theoretical study of these compounds was carried out in order to observe the effect of having different molecular fragments linked to C 2 atom (Fig. 1), over some molecular parameters. The underlined importance over this atom is because of it is flanked by two, more electronegative, atoms (N3-C2-O1) and since it is the electron deficient site, due to double neighboring inductive effect and hence it is also the reactive site. In this line C2 atom acts as electrophilic site and therefore, it suffers the nucleophillic attack of the cyanide ion; due to the latter facts the quantum chemical parameters are hereafter referred to this atom.

Fig. 1. Structure of ( $N, N$-dialkyl-amine)methyl ethers used in the study
Table-1 listed the geometric parameters from optimized structures. Fig. 2 showed the optimized structures. As can be seen from Fig. 2, all the structures present a symmetry-plane $(\sigma)$ that cross through the O 1 atom. The presence of this symmetry plane in the optimized structures is in accordance with the signal pattern observed in the experimental ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra ${ }^{5}$. In compound 4 there exists an interesting proximity of the aromatic rings, in which the HA-HB bond distance was of $2.326 \AA$, whereas in $\mathbf{1}$ the bond distance between both aromatic rings was of $6.82 \AA$. This bond distance is shorter in $\mathbf{4}$ due to ethylene moiety, which is bonded to the aromatic rings and lends more flexibility for this fragment, whereas in 1, this flexibility is more restricted due to the presence of a benzyl moiety (R1 moiety). Thus, when other $\mathrm{CH}_{2}$ unit was added to the benzyl fragment (this implies another degree of freedom in the chemical structure), the distance between both aromatic rings decreased approximately to $1.7 \AA$. In this case, both rings are almost in the same plane. Then, the addition of an ethylene fragment causes an inherent proximity of aromatic rings. Furthermore, from Table-1, the presence of $n$-butyl or $t$-butyl fragment provokes a decrease in the energy value, which could be attributed mainly to nonbonded interactions like steric hindrance.

Fig. 2. Optimized structures for 1-4
The ${ }^{13} \mathrm{C}$ NMR shielding tensors were calculated using the methodology of Gauge independent atomic orbitals (GIAO) ${ }^{20-23}$ at the B3LYP/6-31G+(d) level. The isotropic shielding values were used to calculate the isotropic chemical shifts $\delta$ referred to TMS; the absolute $\sigma\left({ }^{(13} \mathrm{C}\right)$ of 184.1 ppm reported by Jameson and Jameson ${ }^{25}$ was employed for the obtaining of the calculated chemical shift. Table- 2 shows the theoretical and experimental ${ }^{13} \mathrm{C}$ chemical shifts in ppm of $\mathrm{C} 2, \mathrm{C} 4, \mathrm{C} 5$ and C 7 for all the compounds.

## TABLE-2

As was mentioned above, C2 atom has an electronic deficiency and is susceptible to suffer a nucleophilic attack; taking this into account, the atomic charge for this atom was obtained by using a Mulliken population analysis (MPA) and electrostatic potential analysis (ESP) ${ }^{27,28}$. Mulliken population analysis results are well known to strongly depend on the choice of the molecular basis set. Despite its known deficiencies, the Mulliken population analysis is still widely used, owing to its simplicity. In electrostatic potential analysis, atomic partial charges are selected to reproduce the molecular
electrostatic potential. In this respect, Table-3 listed the atomic charge values $\left(\mathrm{q}_{\mathrm{k}}\left(\mathrm{N}_{0}\right)\right)$ for $\mathbf{1 - 4}$ for Mulliken population analysis and electrostatic potential analysis. Mulliken population analysis gave a negative value for $\mathbf{1 - 4}$, which could be related with the employed theoretical level, however, for electrostatic potential only $\mathbf{1}$ showed a negative value, whereas $\mathbf{4}$ showed the highest positive value. The Mulliken population analysis atomic charges analyzed at the nitrogen atoms have positive values, whereas the charges obtained from electrostatic potential gave $-0.1678,-0.0657,-0.7214$ and -0.3573 for $\mathbf{1 - 4}$ compounds, respectively. Again, the absolute differences in the values obtained for Mulliken population analysis and electrostatic potential are due to the employed basis set.

We carried out the calculation for the obtaining of the local softness value. In this case, only the $\mathrm{s}^{+}$parameter was calculated because it shows the more susceptible center to be attacked by a nucleophilic species. The $\mathrm{f}^{+}$and $\mathrm{s}^{+}$values obtained by Mulliken population analysis and electrostatic potential analysis for compounds 1-4 are listed in the Table-3. As can be observed from this table, the $\mathrm{s}^{+}$value directly depends on the $\mathrm{R}^{1}$ substituent attached to N 3 , which affects the reactivity towards the C 2 site. For Mulliken population analysis, the $\mathrm{s}^{+}$ value increases in the following way: $\mathbf{3}, \mathbf{4}, \mathbf{1}$ and $\mathbf{2}$; whereas for electrostatic potential analysis the reactivity increases as: $\mathbf{3}, \mathbf{2}, \mathbf{1}$ and 4 . This difference is because the Mulliken population analysis is highly dependant on the employed basis set. Regarding to electrostatic potential analysis it shows the same order than that of the yield, therefore, the substituent on N3 atom has a great effect in the reactivity of electrophilic center, C2 and therefore in the yield of the chemical reaction and thus scavenging activity.

Finally, the $\Delta f(r)$ values (Table-3) for all compounds were higher than zero, which show that C 2 atom is an electrophilic site; having the same behaviour found by the local softness values.

On the other hand, we carried out a study of quantitative structure-activity relationship, in order to observe which structural and electronic parameters are the most important in these compounds. However, because only four compounds are taken into account in this work, several parameters and combinations between them have been considered to ponderate the number of compounds. The parameters that were taken into account were: N3-C2 and C2-O1 bond lengths, Еномо, $\mathrm{E}_{\text {Luмо }}$ and GAP
energies, dipolar moment (DIP), partition coefficient ( $\log \mathrm{P}$ ), C 2 atomic charge $\left(\mathrm{AC}_{\mathrm{ESP}}\right)$, local softness ( $\mathrm{s}^{+}{ }^{\text {ESP }}$ ), global hardness $(\eta)$, electronegativity $(\chi)$ and ${ }^{13} \mathrm{C}$ NMR chemical shift. Atomic charge and local softness from Mulliken population analysis were not taken into account because, this population analysis strongly depends on the employed basis set. Table-4 listed all the parameters for this study regarding compounds 1-4. Furthermore, the data presented in Table-5 (correlation matrix) express that the electronegativity ( -0.9696 ), N3-C2 bond length ( 0.8355 ) and local softness $(0.8244)$ descriptors correlate well with the $\log$ Eff. Thus a linear combination model was selected due to its simplicity and thus facility in evaluation of those weighed molecular indexes in charge of a particular activity. This simple equation was constructed considering 4 to 10 parameters and was solved by using the multivariate least squares procedure present in Excel software. Those combinations where the dependent parameters $\mathrm{E}_{\text {номо }} / \mathrm{GAP}$, $\mathrm{E}_{\text {LUMo }} / \mathrm{GAP}$ and $\mathrm{AC}_{\text {ESP }} / \mathrm{s}^{+}$ESP are present were not considered for the study. All the 4 parameter systems were resolved adding a dummy constant in the equation in order to avoid the presumably and misestimated analytic solution of the square matrix. All equations were matched to the experimental log Eff. After obtaining the $R^{2}$ and $\mathrm{R}^{2}{ }_{\text {adj }}$ values for all the arrays, there were only considered those, which have the lower $\mathrm{R}^{2}$ and $\mathrm{R}^{2}{ }_{\text {adj }}$ values (values in the range of $1 \mathrm{E}-5$ and 1E-10, respectively). Subsequently, the linear regression for obtaining the Fisher variance ratio ( F ) value was performed and the runs with the higher F value were taken into account. A total of 1290 combination were done, obtaining a F value in the range of $1 \mathrm{E}+25$ and $1 \mathrm{E}+37$. Table-6 listed the runs with the lowest and the highest F values considering from 4 to 10 parameters in the linear combination model. Considering only four parameters could take a risk, seeing as the combination of parameters could give a good F value or a worse value. By contrary wise, having 8,9 , or 10 parameters, provoked a dropping in the F value, hence, in this type of compounds using more than seven parameters should be avoided. The runs 259, 517, 937, 1063 and 1214 show an F value, which is between $2.95 \mathrm{E}+37$ and $8.85 \mathrm{E}+37$; the equations for those runs are shown in the Table7. As can be seen, only the $\mathrm{AC}_{\text {ESP }}$ parameters appear in all those runs, pointing out the importance of this parameter in the scavenging activity; whereas, the local softness is absent in those ones. Owing to this fact, the $\mathrm{s}^{+}$ESP could be omitted in

| *Values in parentheses are the difference between the $\log$ Eff and the $\log E f f$ |  |  |  |  |  |  |

this study, which would reduce the amount of runs, even though, as was mentioned above, the local softness showed a well relation with the log Eff. Regarding the other two parameters, $\chi$ and N3-C2, the last one is only considered in runs 1063 and 1214. Besides, although the highest F value was found with 5 parameters, a combination of 6 parameters and even seven parameters could be taken into account, seeing that those gave an acceptable value of F . Table- 8 shows the experimental and calculated $\log$ Eff values for runs 259, 517, 937, 1063 and 1214, in where it can observe the high correlation between experimental and theoretical values.

On the other hand, an evaluation of the weighed molecular indexes was done for the runs $259,517,937,1063$ and 1214. Thus, the F values calculated when a single parameter in the equations (1) to (5) was eliminated, are listed in Tables 9-13.

|  | 2.1489 | 0.3781 |  |  |
|  | 3.0839 | 1.1108 |  |  |

In run 259, GAP index show to have the main contribution in this equation, whereas the $\log \mathrm{P}$ has a minor contribution.

For run 517, the C2-O1 bond showed to be the index with more weight in this run, although it gave a good $\mathrm{R}^{2}$ value and
furthermore, the higher F value. On the contrary, $\mathrm{E}_{\text {номо }}$ showed to be the parameter with less importance in this run. Regarding run 937, the partition coefficient $(\log \mathrm{P})$, quite the opposite to run 259 , presented to be the parameters most important in this equation.

| TABLE-10 <br> EFFICIENCIES CALCULATED AND R ${ }^{2}$ VALUES WHEN ONE PARAMETER IS ELIMINATED FOR RUN 517 $\log \mathrm{Eff}=2.66-2.53 * \mathrm{C} 2-\mathrm{O} 1-0.13 * \mathrm{E}_{\text {номо }}+64.88^{*}$ $\eta-0.33 * \mathrm{AC}_{\mathrm{ESP}}+0.03 *{ }^{13} \mathrm{C}$ |  |  |  |  |

|  | -0.7336 | 1.0372 |  |  |
|  | -0.6929 | 1.2802 |  |  |

In run 1063, excepting the energy of the frontier orbitals, the other parameters seemed to have the same importance in this equation.

Finally, in run 1214, again the $\log \mathrm{P}$ was the parameter, which most affected the Eff calc value. Therefore, the index, which has more weight in each equation, depends on the array of parameters that was taken into account.

## Conclusion

Even though that the set of compounds is small, this piece of work is related to the statistical significant molecular indexes

in order to determine and rationalize the structural and physicochemical features to obtain a certain activity of compounds type bis-(aminomethyl)ethers, which are employing in the oil industry. Thus, chemical reactivity descriptors, such as Fukui functions, local softness and $\Delta f(\mathrm{r})$ descriptors, calculating from NPA populational analysis, have shown to explain in good way the experimental behaviour of cyanides scavengers. Beside this, the reactivity of the electrophilic carbon atom (C2) can be modulated thought electronic and steric effects, which could permit to design new prototypes of cyanides scavengers with overcome performance. Finally, even only four compounds were considered in this work, the developed structure-activity study indicates that the eqn. 2, showing in Table-7, gives the best correlation for kind of compounds.

## ACKNOWLEDGEMENTS

The present study was supported by Institute Mexicano del Petróleo, Programa de Ingeniería Molecular with project number: D. 00178 and D. 00402.
